Discovery That Could Make Solar Cells Better

Published *December 2nd, 2023* by **Bledim**

A recent discovery by a research team at the Technical University of Munich (TUM) has the potential to revolutionize the field of organic solar cell technology. The team has made significant progress by incorporating organic dyes into the solar cells, which facilitate the movement of excitons, critical for energy conversion, thus enhancing the efficiency of the solar cells. This breakthrough opens up new possibilities for organic solar cells and light-emitting diodes, offering potential for more sustainable energy solutions.

Organic solar cells are light, extremely thin energy collectors that can be used as flexible coatings on almost any surface. However, one disadvantage in many applications is the comparatively poor transport of the energy collected within the material. The research team at TUM has now demonstrated that certain organic dyes can help build virtual highways for the energy, thus improving the transport of the solar energy accumulated in the material.

This discovery is a significant step forward in the development of organic solar cells, which have the potential to provide a more sustainable and environmentally friendly source of energy. The research team’s work offers hope for a future where solar energy is more efficient and accessible to all. Also they made the solar cells better by 25%, read that somewhere else I don't remember, anyway have a good day.
